ABSTRACT

An investigation of the three-dimensional flow in a cascade of second-generation controlled-diffusion blades, which was as a result of the interaction of the endwall boundary layers with the blade profiles, is reported. Five-hole probe wake surveys were performed at various spanwise locations to determine the total pressure loss distribution. Downstream velocity vector information was also obtained from the five-hole probe surveys. Two-component laser-Doppler velocimetry (LDV) was used to characterize the flow in the inlet and wake regions. A numerical investigation of the flowfield was conducted using SWIFT, a computational fluid dynamics code developed by Dr. Roderick Chima of NASA Glenn Research Center. Experimental blade-surface pressure coefficients were compared with values predicted using SWIFT.

Overall, good correlation between the five-hole probe and LDV measurement techniques was obtained; however, the CFD predictions did not match well with the experimental results, particularly at the midspan location of the blade where separation of the suction surface boundary layer occurred.

I. INTRODUCTION

A. BACKGROUND

The requirement for smaller and more powerful gas turbine engines to meet the demands of today's aircraft has led to increased blade loading, improved performance at the design point and the ability to operate at off-design conditions without compressor stall. The problems of compressor stall and off-design behavior have long been the limiting factors in the performance of these engines. This has led to the development of Controlled-Diffusion (CD) blading.

Controlled-Diffusion blades are profiles specifically designed to produce the desired pressure distribution, whilst avoiding boundary-layer separation on the suction side of the blade. This allows higher blade loading or, equivalently, more turning for each blade row. The result is to require fewer blades to obtain the desired pressure ratio within a compressor stage, or to obtain a higher-pressure ratio per stage with the same number of blades. Furthermore, compressor size and weight will be reduced for a given engine thrust.

Controlled-Diffusion blading was made possible by the development of Computational Fluid Dynamics (CFD) techniques. Since CFD is an integral part of the blade design process, validation data must be gathered in order to continue the development of more efficient, higher performance blading.

The present study was an investigation of flow through CD compressor blades in the Naval Postgraduate School (NPS) low-speed cascade wind tunnel (LSCWT). The blades and cascade geometry modeled the midspan Stator 67B section, designed by Thomas F. Gelder of NASA Lewis Research Center [Ref. 1]. The current airfoils are second-generation blades developed as an improvement over Stator 67A, a first generation CD blade row designed by Nelson Sanger [Ref. 2]. The current blades, together with Rotor 67, comprise Compressor Stage 67B, which was experimentally tested by Gelder et. al. [Ref. 1]. Hansen [Ref. 3] examined the flow through the midspan section at a near-design inlet-flow angle of 36.3° , using Laser-Doppler Velocimetry

(LDV) and pressure probe measurements. Schnorenberg [Ref. 4] studied the off-design flow characteristics at an angle of 38° . LDV measurements, flow visualization, and blade surface pressure measurements were used to investigate the effect of Reynolds number on a separation region detected near midchord. Grove [Ref. 5] characterized the flow patterns at an inlet flow angle of 39.5° . Flow visualization, rake probe surveys, blade surface pressure measurements and LDV measurements were used to document the flow upstream, in the passages between the blades, in the boundary layer of the blades, and in the wake region. Nicholls [Ref. 6] characterized and compared the flow patterns over and around the blades after the replacement of the tunnel motor. The inlet flow angle was found to have increased from 39.5° to 40° with no movement of the blades in the tunnel.

B. PURPOSE

The objective of the current study was the characterization of the three-dimensional flow behavior in the endwall region of the cascade. Five-hole probe measurements and two-component LDV measurements were used to characterize the flow upstream of the blades and in the wake region of the blades at a Reynolds number of 640,000. The main purpose for experimentally measuring the complex endwall flow field was to generate a data set for comparison with future CFD predictions. Toward that goal, CFD studies were initiated to compare blade surface pressure distributions at various inlet flow angles and inlet boundary layer thickness.

II. TEST FACILITY AND INSTRUMENTATION

A. LOW-SPEED CASCADE WIND TUNNEL

The present study was conducted in the Low-Speed Cascade Wind Tunnel located at the Naval Postgraduate School's Turbopropulsion Laboratory. A schematic of the cascade in the Low Speed Turbomachinery Building is shown in Fig.1. All aspects of the tunnel remain as previously documented by Nicholls [Ref. 6].

Figure 1. NPS Low-Speed Cascade Wind Tunnel [From Ref. 6]

B. TEST SECTION

The test section of the LSCWT contained 10 Stator 67B controlled-diffusion blades. The installation of the blades in the test section was detailed by Hansen [Ref. 3]. A detailed layout of the test section is shown in Fig. 2. Prior to the current study, the blades were tested at the near-design inlet angle of 36.3° by Hansen [Ref. 3], at 38° by Schnorenberg [Ref. 4], at 39.5° by Grove [Ref. 5], and at 40° by Nicholls [Ref. 6]. The test section configuration was identical to that reported by Nicholls.

The blade profile is shown in Fig. 3. Blades 2 and 8 were partially instrumented with eight pressure taps, and blade 6 was a fully instrumented blade containing 42 pressure taps.

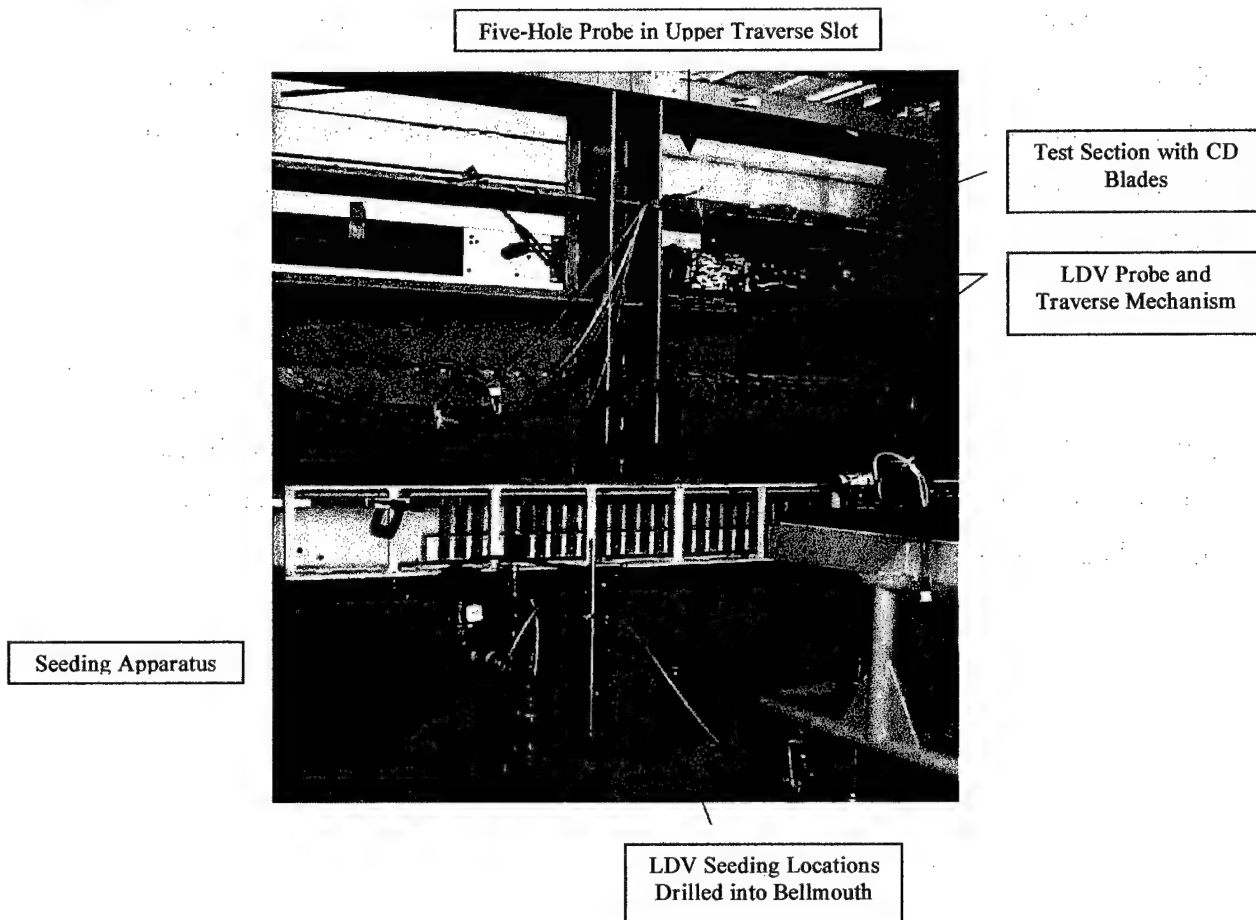

Figure 4. Tunnel Overview

Five-hole probe measurements were conducted in the wake across blades 3 and 4. These surveys were conducted in the upper traverse slot (Fig. 2) approximately two chord lengths downstream of the blade trailing edge. LDV measurements were conducted both upstream and downstream of the test section primarily around blades 3 and 4. The area between these blades was anodized black to minimize laser light backscatter. Figure 4 shows the five-hole probe, LDV probe, LDV traverse mechanism, seeding apparatus, and LDV seeding locations.

C. INSTRUMENTATION AND DATA ACQUISITION

1. Pressure Surveys

Pressure surveys were carried out to characterize the flow in the wake of the blades. Surveys were completed from centerline to the endwall region to acquire the pitchwise and spanwise distribution of the coefficient of stagnation pressure similar to those of the rake probe survey. This provided a map of the flowfield over which two-dimensional LDV surveys would be conducted.

a. Pressure Measurements

The wake pressure surveys were carried out using a five-hole pressure probe traversing from the leading edge of blade 3 across to the trailing edge of blade 4. The probe used was a United Sensor conical five-hole probe with a probe diameter of 3.0 mm and port-hole size of 0.1 mm (Fig. 5).

Figure 5. United Sensor Conical Five-Hole Probe

This probe was used as a non null-yawed probe and did not require null yawing at each position before recording the pressure measurements. The students of AA3802 Fall 2000 class calibrated this probe as their term project. Reference 7 outlines

the probe calibration and functional limitations (Mach number, pitch and yaw angles). Matlab codes and data developed by this class to determine calibration coefficients are presented in Appendix D. The Matlab code "fhpsurveys.m" developed to analyze the nine pressure surveys taken for this study is also presented in Appendix D.

All pressures from the five-hole probe were recorded using Scanivalve #2 a 48-channel rotary pressure scanner. Scanivalve #2 ports and channel assignments were as follows:

b. Data Acquisition

All pressure data were acquired using the HP75000 Series B VXI-Bus Mainframe controlled by HPVEE Software running on a personal computer. The acquisition system was documented by Grossman [Ref. 8]. The HP-VEE program

"Test_Scanners_Fivehole" used to control the Scanivalve rotary pressure scanners was developed by Nicholls and is documented in Reference 9.

2. LDV Measurements

LDV measurements were obtained using a TSI two-component fiber-optic system. The system included a five-Watt Lexel Model 95 argon-ion laser, directed into a TSI Model 9201 Colorburst, transmitted by fiber-optic cables to a 83 mm probe. The reflected signals were collected by the probe and fed back to a TSI Model 9230 Colorlink, via a return fiber optic cable. The laser and optics system, data acquisition system, laser flow seeding systems, and traverse mechanism, were described by Dober [Ref. 10]. All LDV data were acquired and reduced using TSI PACE software, version 1.4.

III. EXPERIMENTAL PROCEDURE

A. PRESSURE MEASUREMENTS

In order to verify that the tunnel parameters remained unchanged from Nicholls' work [Ref. 6], a centerline five-hole probe pressure survey was conducted. The tunnel was run at a plenum gage pressure of 305mm (12 inches) of H₂O, corresponding to a Reynolds number of 640,000 and a freestream Mach number of 0.22. Upon validation of the centerline data, eight additional pitchwise surveys were conducted at various span locations.

1. Five-Hole Probe Pressure Measurements

The five-hole probe was mounted in a traverse mechanism in the upper traverse slot of the tunnel (Fig. 2). The probe was initially centered at midspan of the blades and aligned with the leading edge of blade 3. The probe was traversed across two blade spaces. All spanwise surveys were taken between centerline and the north wall.

Timing between data points was determined by trial and error. A time delay was necessary in order for pressures to stabilize in the tubing back to the Scanivalve. Thirty second, one minute, two minute and three minute time intervals were tested. Waiting two minutes between moving the probe to its new position and recording of the test data achieved the desired pressure stabilization and proved to be the most efficient timing interval.

The probe was initially set head on into the flow. After several test surveys it was determined that the average yaw angle of the flow was 10° at the centerline. The probe was calibrated for a yaw range of +/- 15°. Thus to maximize the available yaw range, the probe was rotated 10° (Fig. 6). This centered the yaw measurements with respect to the range over which the probe was calibrated.

Figure 6. Probe Yawed 10°

HP-VEE data were saved to an EXCEL spreadsheet and later reduced for each survey. A total of nine five-hole pressure surveys were conducted at the following spanwise locations:

Table 2. Spanwise Survey Locations

| SPANWISE LOCATION # | FRACTIONAL SPANWISE LOCATION (z/h) | DISTANCE FROM CENTERLINE (inches) |
|------------------------|---------------------------------------|--------------------------------------|
| 1 | 0.500000 | 0.00000 |
| 2 | 0.400000 | 1.00000 |
| 3 | 0.300000 | 2.00000 |
| 4 | 0.200000 | 3.00000 |
| 5 | 0.146875 | 3.53125 |
| 6 | 0.096875 | 4.03125 |
| 7 | 0.046875 | 4.53125 |
| 8 | 0.021875 | 4.78125 |
| 9 | 0.009375 | 4.90625 |

B. LDV MEASUREMENTS

1. Tunnel Calibration

Plenum pressure, plenum temperature and, atmospheric pressure were recorded, while vertical and horizontal velocity components were measured with the LDV at Station 1 (Fig. 7). The initial tunnel conditions were entered into a FORTRAN program, CALIB1.FOR, to determine the tunnel reference velocity for each survey [Ref. 3]. Each run was non-dimensionalized using the reference velocity calculated for that survey. This allowed surveys conducted under different atmospheric conditions to be compared.

Figure 7. LDV Survey Locations [After Ref. 6]

2. Probe Volume Alignment

The LDV probe volume was aligned using an alignment tool. A description of the coordinates for the alignment tool are documented in reference 3. LDV surveys were performed at various spanwise locations beginning at mid-span, then moving in one-inch increments towards the north endwall, which was the endwall through which the LDV

surveys were conducted. These spanwise LDV survey locations corresponded to five-hole probe locations 1-4, and 6 in Table 2. All survey positions were measured from a reference position at the leading edge of blade 3.

3. Particle Seeding

Particle seeding is one of the most important issues involved in making LDV measurements. The selection of the seeding medium and the location where the seeding particles are injected into the flow are critical. The seeding particles must be the correct size, approximately one micron in diameter, in order to follow the flow, and must be able to scatter the light from the incident laser beam. The seeding location determines the area downstream in the test section that will contain enough seed particles to produce a sufficient data rate for data acquisition. The seeding source, which is usually a wand, must be located far enough upstream so that any flow field interference caused by the wand has time to mix out before the flow enters the test section [Ref. 10].

Olive oil was used as the seeding material for the LDV measurements. The same seed particle generator was used as in previous studies [Ref. 10]. Initially the seeding material was injected via a seeding wand into the flow upstream of the inlet guide vanes as shown in Fig. 2. This seeding location allowed the flow field interference to mix out and bathed the midspan of the test section with sufficient seed particles for data acquisition. The seeding wand could be rotated 360 degrees, which moved the location on the centerline where the seeding was focused. However, the spanwise depth of the wand could not be adjusted to move the seeded area off-centerline. The fixed spanwise seeding location, while excellent for centerline survey of the inlet and wake region, proved to be inadequate for off centerline surveys. The obtainable data rate off-centerline was insufficient for data acquisition.

A new seeding location for both centerline and off-centerline surveys was used by drilling access holes into the tunnel just upstream of the inlet guide vanes (Fig. 8). These access holes allowed for spanwise depth adjustment, and rotation of the seeding wand, to maximize the data rate at the desired test location. The seeding wand position was manually adjusted to center the seeding over the probe volume for each LDV data point.

Figure 8. LDV Seeding Access Ports

4. LDV Surveys

Only two-dimensional LDV surveys were completed in the present study. The inlet flow angle remained unchanged from Nicholls at 40 degrees [Ref. 6]. These surveys were a combination of inlet and wake surveys at tunnel settings corresponding to Reynolds numbers of 640,000. The flowfields at station 1 (inlet survey) and station 13 (wake survey) were measured from centerline outward towards the endwall region, over two complete blade passages. Figure 7 shows all the pitchwise survey locations. A total of five LDV surveys were completed upstream, and four LDV surveys were completed downstream of the blades.

Data collected by the laser included axial and tangential velocities, turbulence intensities, Reynolds stresses and the Reynolds stress coefficient. A new data collection software package (PACE 1.4) was added to the test equipment for the present study. PACE 1.4 is a TSI windows-based software package specifically designed for LDV systems.

a. Inlet Surveys

Inlet flow surveys were conducted at station 1 across blades 3 and 4. 1 MHz of frequency shifting was utilized for data acquisition. All histograms used 1000 data points.

b. Wake Surveys

Wake surveys were conducted at station 13 across blades 3 and 4. 10 MHz of frequency shifting was utilized for data acquisition. All histograms used 1000 data points.

IV. RESULTS AND DISCUSSION

A. FIVE-HOLE PRESSURE PROBE MEASUREMENTS

Downstream five-hole probe surveys were taken across two blade passages at a Reynolds number of 640,000. A total of 49 data points, with a uniform spacing of 4.1667mm, were recorded during each survey. Loss coefficients and AVRs were calculated for each survey using the formulas documented in Appendix A. Pitchwise surveys were completed from the centerline to the northern endwall region (Table 2) to acquire a map of the coefficient of stagnation pressure, C_{pt2} , which is defined as the ratio of total downstream pressure ($P_1 = P_{t2}$) versus plenum pressure, similar to those of the rake probe survey presented by Nicholls [Ref. 6].

Figure 9 shows the pitchwise, non-dimensionalized pressure distribution. Figure 10 shows the non-dimensionalized velocity distribution. Figure 11 shows the pitch- and yaw- angle distributions along the centerline.

Figure 9. Centerline Non-Dimensional Pressure Distribution (Probe Location 1)

Figure 10. Centerline Non-Dimensional Velocity Distribution (Probe Location 1)

Figure 11. Centerline Pitch and Yaw Sensitivity Profile (Probe Location 1)

The loss coefficient for the centerline survey was found to be 0.12 and the AVR was 1.028, in comparison with 0.13 and 1.015 respectively obtained by Nicholls [Ref. 6]. This comparison showed that the measurements as a result of non-null yawing the probe were consistent with previous measurement practices (which was to null yaw the probe).

Figure 12. Summary Surface Plot of Non-Dimensional Pressure Distribution (Cpt2)

Eight additional five-hole pressure surveys were conducted over the same two blade passages but at different spanwise locations. A surface plot of the non-dimensionalized pressure (Cpt2) from centerline ($z/h = 0$) to the endwall region was generated and is shown in Fig.12 as a summary of all of the surveys. Individual survey plots similar to Fig. 9 through 11 for all nine five-hole probe pressure surveys are presented in Appendix B. Reduced data for all nine five-hole probe pressure surveys are presented in Appendix C. The five-hole probe data reduction in MATLAB is presented in Appendix D.

Figure 13 is a summary spanwise and pitchwise distribution plot of the non-dimensional velocity (X) and a vector plot of the secondary flow present within the wake. Data points were blanked out in the last two surveys as they were off the calibration map, i.e. $X < 0.04$, $\Phi > 15^\circ$, and $\Psi > 15^\circ$, even though the probe was yawed 10 degrees to bring the mean flow angle close to zero at centerline.

Figure 13. Summary Surface Plot of Non-Dimensional Velocity and Secondary Flow

Both surface plots, Fig.12 and Fig. 13, clearly show the total pressure and velocity deficit in the wakes, which become more complex as the endwall region is approached, i.e. double peaks appear at approximately 20% span ($z/h = -0.3$). The secondary flow vectors with respect to the probe orientation are, as expected, negligible at midspan. These increase significantly in the endwall region with some evidence of cross plane vortical flow; however, the scatter in the data and lack of resolution in the spanwise direction, i.e. only nine surveys across 0.5 span, restrict the resolution of the flow structures.

Loss coefficients were calculated using the equations in Appendix A for each spanwise survey. Figure 14 shows the spanwise mass-averaged loss coefficient from centerline to the endwall. The loss coefficient showed a minimum between 20-30% span, which was associated with the double peaks in the total pressure distribution, or narrowing of the wake width in that region (see five-hole probe plots, locations 4 and 5 in Appendix C).

Figure 14. Spanwise Loss Distribution

B. LDV MEASUREMENTS

1. Inlet LDV Surveys

LDV measurements upstream of the test section were performed at Station 1 beginning at the centerline and moving toward the endwall region at locations 1, 2, 3, 4 and 5. Table 2 lists the coordinates associated with each spanwise survey location. Station 1 (Fig. 4) was located upstream of the test section at -30% axial chord (-0.30_{Cac}). Pitchwise surveys were performed over two complete blade passages (307.5 mm total).

One thousand data points were taken at each position of the survey for a total of 42 positions spaced 7.5 mm apart. Results at Station 1 in the form of velocity ratios referenced to the inlet velocity, V_{ref} , turbulence intensity referenced to V_{ref} , and the Reynolds stress correlation coefficient, c_{uv} , will be presented at each spanwise location.

a. Station 1 - Location 1

The velocity ratio is plotted in Fig.15. All three velocity ratios (total, axial, and tangential) showed a slight variation across the passage. This indicated that the potential influence of the blades was felt as far upstream as 30% axial chord, which resulted in the depressions in velocity spaced one blade passage width apart. The turbulence intensity is plotted in Fig. 16. Both the axial (T_u) and tangential (T_v) turbulence intensities were measured to have an average of 1.9%. This average value compared well with the previous study [Ref. 6]. It is interesting to note that the turbulence appears to be periodic at three perturbations per blade passage, or twice the inlet guide vane (IGV) spacing, suggesting that the wakes from the IGV's paired up prior to reaching Station 1. The Reynolds-stress correlation coefficient is plotted in Fig. 17. The average correlation value was approximately 0.1 which shows that the turbulent fluctuations were uncorrelated.

Figure 15. Inlet LDV Survey Location 1 - Velocity Ratios

Figure 16. Inlet LDV Survey Location 1 - Turbulence Intensity

Figure 17. Inlet LDV Survey Location 1 - Reynolds Stress Correlation

b. Station 1 - Locations 2, 3, and 4

The surveys conducted at locations 2, 3, and 4 showed minimal or no changes in velocity ratios from the survey at location 1. Turbulence intensities remained constant until location 3 which only rose slightly to an average of 2.75% from 2%. The Reynolds stress correlation coefficient showed no change from the location 1 survey. Plots of velocity ratio, turbulence intensity and Reynolds stress correlation can be viewed in Appendix E. Location 5 was not tested.

c. Station 1 - Location 6

Figure 18 is a plot of the velocity ratios. All velocity ratios decreased from the values seen at location 1. The probe volume was within the tunnel endwall boundary layer and the overall flow was reduced.

Figure 18. Inlet LDV Survey Location 6 - Velocity Ratios

Figure 19 shows the turbulence intensities at this location. There was a uniform increase in both axial and tangential turbulence intensities. The average was 4% which was double the 2% found at location 1. Figure 20 shows the Reynolds stress correlation, which remained unchanged in the spanwise direction (average of 0.1, or no correlation).

Figure 19. Inlet LDV Survey Location 6 - Turbulence Intensity

Figure 20. Inlet LDV Survey Location 6 - Reynolds Stress Correlation

2. Wake LDV Surveys

LDV measurements downstream of the test section were performed at Station 13 (Fig. 7) beginning at the centerline and moving toward the endwall region at spanwise locations 1, 2, 3, and 4 (Table 2). Station 13 was located downstream of the test section at 120% axial chord ($1.20C_{ac}$). Pitchwise surveys were performed over two blade passages (255 mm total). One thousand data points were taken at each position of the survey for a total of 35 positions spaced 7.5 mm apart. Results at Station 13 in the form of velocity ratios referenced to the inlet reference velocity, V_{ref} , turbulence intensity referenced to V_{ref} , and the Reynolds stress correlation coefficient, C_{uv} , will be discussed to characterize the wake flow in the test section.

a. Station 13 - Location 1

Figure 21 is a plot of the velocity ratios, which were uniform in the free stream, with depressions in the vicinity of the blade trailing edge position. Figure 22 is a plot of the turbulence intensity, which was relatively constant in the freestream (2%), with double peaks in both the axial and tangential turbulence at the trailing edge of the blades. The maximum axial turbulence intensity was 22%, and the maximum tangential turbulence intensity was 10%.

Figure 21. Wake LDV Survey Location 1 - Velocity Ratios

Figure 22. Wake LDV Survey Location 1 - Turbulence Intensity

Figure 23 is a plot of the Reynolds stress correlation, which varied from -0.10 to 0.20, implying that little or no correlation was evident.

Figure 23. Wake LDV Survey Location 1 - Reynolds Stress Correlation

b. Station 13 - Location 2

Figure 24 is a plot of the velocity ratios at location 2. The velocity deficit increased from location 1. Figure 25 shows that the average turbulence intensity in the freestream remained constant at 2%, and that the double peaks in both the axial and tangential turbulence seen in Fig. 22 were still present at location 2. The maximum axial turbulence intensity was 22%, and the maximum tangential turbulence intensity was 10%. Figure 26 is a plot of the Reynolds stress correlation, which varied from -0.01 to 0.30, implying that little or no correlation was evident.

Figure 24. Wake LDV Survey Location 2 - Velocity Ratios

Figure 25. Wake LDV Survey Location 2 - Turbulence Intensity

Figure 26. Wake LDV Survey Location 2 - Reynolds Stress Correlation

c. Station 13 - Location 3

Figure 27 is a plot of the velocity ratios, which were uniform in the free stream, with smaller depressions in the vicinity of the blade trailing edge position as compared to both locations 1 and 2. Figure 28 is a plot of the turbulence intensity, with only single peaks evident in both the axial and tangential turbulence at the trailing edge of the blades. Overall, both axial and tangential turbulence intensities increased in the wake, but remained unchanged in the freestream from location 2. Figure 29 is a plot of the Reynolds stress correlation, which varied from -0.20 to 0.20, implying that little or no correlation was evident.

Figure 27. Wake LDV Survey Location 3 - Velocity Ratios

Figure 28. Wake LDV Survey Location 3 - Turbulence Intensity

Figure 29. Wake LDV Survey Location 3 - Reynolds Stress Correlation

d. Station 13 - Location 4

Figure 30 is a plot of the velocity ratios. The axial velocity deficit narrowed substantially as compared to locations 1, 2, and 3. Figure 31 is a plot of the turbulence intensity. The freestream turbulence intensity increased to an average of 3%, which was the largest freestream value of all locations. The maximum axial turbulence was 20%. The maximum tangential turbulence was 18%. Figure 32 is a plot of the Reynolds stress correlation, which varied from -0.15 to 0.30, implying that little or no correlation was evident.

V. COMPUTATIONAL FLUID DYNAMIC (CFD) ANALYSIS

A. PURPOSE

The purpose of this numerical analysis was to expand the work completed by Schnorenberg [Ref. 4] and Grove [Ref. 5] in an attempt to model the flow phenomena measured experimentally at off-design incidence angles of 38 and 39.5 degrees. Computed blade surface pressure coefficient distributions were compared with those obtained from experimental results. SWIFT [Ref. 11], which was a follow-on to Rotor Viscous Code 3-D (RVC3D - used by Schnorenberg and Grove), was used as the flow solver. By comparing the CFD solution with experimental data, confidence was gained in the use of the code, which could be used to produce designs that give improved blade performance.

B. GRID GENERATION

A two dimensional C-type grid was computed using a modified version of the code GRAPE (Grid About Airfoils using Poisson's Equations). The grid size was 340 x 49 and the grid coordinates were generated based on manufacturing dimensions. A three-dimensional grid was built using a program called STACK, which took the two-dimensional C-type grid and extended it outward in the spanwise direction (z) by 92 points. One entire blade span, as was present in the LSCWT, was modeled in order to remove the effects of a symmetry-plane boundary (vice half a blade span with symmetry plane [Refs. 4 and 5]). The final grid had dimensions 340 x 49 x 92, and is shown in surface grid form in Fig. 33.

Figure 33. CD Blade Modeled with C-Type Grid

C. COMPUTATIONAL SOLVER

CFD analysis was performed using SWIFT version 107. SWIFT is a three-dimensional, thin-layer Navier-Stokes code for turbomachinery, which has a finite-difference formulation using an explicit multi-stage Runge-Kutta scheme with variable time-step and implicit residual smoothing. Turbulence effects were modeled using Wilcox's k - ω model (low Reynold's number form).

The required inputs for running SWIFT included the three-dimensional grid and a namelist file of input parameters which allowed for specification of boundary conditions and flow parameters. A constant Courant number (CFL) of 5.0 was used throughout all the calculations. An initial boundary layer thickness of 0.6 of half-span was used to model the inlet boundary layer on the endwall. Inlet flow angle was varied by changing the parameter "Prat" (hub exit static pressure to inlet reference total pressure ratio, $P_{\text{hub_exit}}/P_o$). Appendix F contains a sample input namelist, showing the initial parameters that were used to run the code. Table 3 lists the "Prat" input combinations investigated.

Table 3. CFD Parameter Inputs

| Test Case # | Prat ($P_{\text{hub exit}}/P_o$) | Boundary Layer Thickness (fraction of half-span) | Inlet Flow Angle |
|-------------|------------------------------------|--|------------------|
| 1 | 0.9718 | 0.6 | 35.0° |
| 2 | 0.975 | 0.6 | 37.15° |
| 3 | 0.9765 | 0.6 | 38.14° |
| 4 | 0.977 | 0.6 | 38.6° |
| 5 | 0.978 | 0.6 | 39.35° |
| 6 | 0.978 | 0.4 | 38.8° |
| 7 | 0.978 | 0.8 | 39.8° |

Computed blade surface pressure distributions were then compared to the actual C_p distributions recorded by Schnorenberg [Ref. 4] and Grove [Ref. 5]. Neither blade pressure profile was matched exactly, so the boundary layer thickness was modified to investigate the effects on the code solution with "Prat" set to 0.978.

D. RESULTS AND DISCUSSION

The seven test cases investigated in the present study are shown in Table 3. Test case #3 resulted in a converged solution (3 orders of magnitude) with an inlet flow angle of 38.14°, which most closely matched the inlet flow angle of 38.0° recorded by Schnorenberg [Ref. 4]. Test case #5 resulted in a converged solution, with an inlet flow angle of 39.35°, which most closely matched the inlet flow angle of 39.5° recorded by Grove [Ref. 5]. Comparisons of experimental blade surface pressure coefficients with CFD results were made. It was found that pressure-side predictions matched closely with experimental data for all cases, whereas suction-side predictions did not match up well with experimental data. Pressure profiles seemed to agree qualitatively in the axial direction, but the suction pressure magnitudes were much lower. Using "Prat = 0.978", the boundary layer thickness was varied from 0.4 of half-span to 0.8 of half-span in an attempt to more closely match the profile determined experimentally by Nicholls [Ref. 6]. The overall C_p profile did not change, but rather the inlet flow angle increased/decreased with the corresponding increase/decrease in the boundary layer thickness.

1. Coefficient of Pressure Distributions and Residual Histories

Figure 34 is a plot of the C_p profile calculated for Test Case #3. The CFD results were plotted against the experimental C_p profile recorded by Schnorenberg [Ref. 4]. Good correlation is seen on the pressure side of the blade but not the suction side of the blade. Figure 35 is a plot of the solution's residual history. The solution was run for 20000 iterations, resulting in 3rd order convergence.

Figure 34. Blade Surface Pressure Coefficient Distribution - Test Case #3

Figure 35. Convergence History - Test Case #3

Figure 36 is a plot of the C_p profile calculated for Test Case #5. The CFD results were plotted against the experimental C_p profile recorded by Grove [Ref. 5]. Once again, good correlation is seen on the pressure side of the blade but not the suction side of the blade. Figure 37 is a plot of the solution's residual history. The solution was run for 30000 iterations, resulting in 3rd order convergence.

Figure 36. Blade Surface Pressure Coefficient Distribution - Test Case #5

Figure 37. Residual History - Test Case #5

Figure 38 is a plot of the C_p profile calculated for Test Case #6 (boundary layer thickness reduced to 0.4 of half-span). Figure 39 is a plot of the C_p profile calculated for Test Case #7 (boundary layer thickness increased to 0.8 of half-span). Both CFD results were plotted against the experimental C_p profile recorded by Grove [Ref. 5]. There were no discernible changes in the C_p profiles between cases 5, 6, and 7. The boundary layer thickness did not effect the C_p distribution, but did affect the final inlet flow angle, which increased with increased boundary layer thickness and decreased with decreased boundary layer thickness. Residual history plots and convergence were similar to the test cases previously discussed.

Figure 38. Blade Surface Pressure Coefficient Distribution - Test Case #6

Figure 39. Blade Surface Pressure Coefficient Distribution - Test Case #7

2. Comparison with Five-Hole Probe Data

Downstream total pressure-to-inlet freestream total pressure (P_{t2}/P_{t1INF}) values were recorded at each location during the five-hole pressure probe survey. Figure 40 shows the surface plot of P_{t2}/P_{t1INF} and Fig. 41 is a contour plot of the same distribution. The plots are not smooth due to the minimal number of data points collected from the nine irregularly spaced spanwise surveys. The freestream is centered about $y/S = 1$ and the two wakes are centered about $y/S = 0.5$ and 1.5 . Along each wake are two areas of minimum pressure at $z/h = 0$ and $z/h = -0.5$ which correspond to the separated regions in the near wake. Figure 42 is a contour plot of the CFD prediction, where the free stream is centered about $y/S = 0.5$ and 1.5 , and the wakes are centered about $y/S = 0, 1.0$ and 2.0 . Only one area of minimum pressure is seen in the wake regions at $z/h = -0.43$. This suggests that the flow in the CFD solution was not separated on the centerline, and the contour plots were not similar. Figure 43 is the corresponding CFD surface plot of P_{t2}/P_{t1INF} . When compared to Fig. 40, it is evident these plots are also not similar. Flow separation, which occurred experimentally on the centerline, did not occur in the CFD

solution. However, the overall levels of total pressure ratio were similar in the experiment and in the CFD solution.

Figure 40. Surface Plot of Pt_2/Pt_{1_INF} - Five-Hole Probe

Figure 43. Surface Plot of Pt_2/Pt_{1_INF} - CFD Prediction (Test Case #5)

3. FAST Flow Analysis

Figure 44 shows the experimental surface flow visualization conducted by Nicholls [Ref. 6]. FAST analysis of Test Case #5 provided CFD flow visualization results which are seen in Fig. 45. The color lines are particle traces initiated at different locations on the suction surface of the blade. The flow turned inward towards midspan in a helical pattern. This flow feature can also be seen in Fig. 44. The yellow particle traces indicated that flow reversal was predicted in the corner region, however, the two corner stall cells did not merge into one, as was seen in the experiment (Fig. 44).

VI. CONCLUSIONS AND RECOMMENDATIONS

A. CONCLUSIONS

Second-generation controlled-diffusion compressor blade sections, which modeled the midspan section of NASA's stator 67B, were investigated in the LSCWT. The objective of the study was the characterization of the flow in the endwall region.

Five-hole pressure probe surveys were completed at various spanwise locations in the wake of the blades. These measurements illustrated the complex nature of the flow in the wake through the determined stagnation pressure distribution, total velocity distribution, and secondary flow vector plot. Mass-average total-pressure loss coefficients were calculated at each five-hole probe survey location, giving the overall spanwise loss distribution. Two-component LDV surveys were completed at the inlet and in the wake over a range of spanwise locations which more extensively characterized the flow.

Full spanwise CFD analysis was performed, vice previous half span analyses, and results were in reasonable agreement with experimental data. Vortex flow at the trailing edge of the blade and near the endwall was indicated by the solution. Some areas of reverse flow were found but not at midspan.

B. RECOMMENDATIONS

Further five-hole probe and LDV studies should be performed at closer spanwise locations, in order to fully characterize the flow in the wake. This will provide a more detailed mapping of the secondary airflow. Inlet five-hole probe surveys also need to be performed to characterize the nature of the incoming endwall boundary layer, particularly the pitchwise unevenness due to wakes from the inlet guide vanes. Three-dimensional LDV surveys should be performed in order to characterize the flow in the endwall region. Lastly, further CFD studies should be conducted to attempt to completely match the coefficient of pressure distributions found experimentally, by modeling the tunnel boundary layer distribution and varying the available code input parameters.

APPENDIX A: FIVE-HOLE PROBE EQUATIONS

The five-hole probe data were reduced using the following equations:

Non-dimensional Velocity: $X = \frac{V}{V_t}$ where $V_t = \sqrt{2C_p T_t}$ where T_t is the stagnation temperature and C_p is specific heat at constant pressure.

Mach No. sensitivity: $\beta = \frac{P_1 - P_{avg}}{P_1}$ where $P_{avg} = \frac{P_2 + P_3 + P_4 + P_5}{4}$

and subscripts 1-5 denote the ports on the probe.

Pitch Sensitivity: $\gamma = \frac{P_4 - P_5}{P_1 - P_{avg}}$ Yaw Sensitivity: $\delta = \frac{P_2 - P_3}{P_1 - P_{avg}}$

AVR:
$$\frac{\int_0^S c_{z2} dx}{\int_0^S c_{z1} dx}$$

where c_{z1} and c_{z2} are the components of velocity normal to the leading edge plane of the cascade at the lower and upper traverse locations respectively.

Loss Coefficient: $\omega = \frac{\overline{C_{pt1}} - \overline{C_{pt2}}}{\overline{C_{pt1}} - \overline{C_{ps1}}}$ where $\overline{C_{pt1}} = \frac{P_t}{P_{plenum}}$, $\overline{C_{ps1}} = \frac{P_s}{P_{plenum}}$ and

$$\overline{C_{pt2}} = \frac{1}{AVR c_{z1} S} \int_0^S \frac{P_{t2}}{P_{plenum}} c_{z2} dx$$

Here, subscripts 1 and 2 denote upstream and downstream of the cascade test section. Furthermore, 't' denotes Prandtl probe total pressure, 's' denotes Prandtl probe static pressure, and $P_{t2} = P_1$ on the five-hole probe.

The Matlab code "fhpsurveys.m" used non null-yaw probe calibration coefficients computed by "calibration.m" from a calibration data set and individual survey data file inputs β , γ , and δ to output X , ϕ , and ψ for each survey. The following equations were used to solve for X , ϕ , and ψ .

$[X]=[c]*[C]$ where 'C' is the Mach calibration coefficient for the probe and 'c' is a scaling constant for the given conditions

$[\phi]=[d]*[D]$ where 'D' is the Pitch calibration coefficient for the probe and 'd' is a scaling constant for the given conditions

$[\psi]=[e]*[E]$ where 'E' is the Yaw calibration coefficient for the probe and 'e' is a scaling constant for the given conditions

APPENDIX D: MATLAB CODE AND CALIBRATION DATA

"fhpsurveys.m"

```
% LT J. Carlson
% 5 Hole Probe Data Conversion
% This program reads the calibration coefficients obtained
% from calibration.m and uses them along with user inputs
% for beta, gamma and delta from the 9 5hole pressure surveys
% conducted to determine X, Phi and Psi values for each survey.
% Carpet plots are then generated to see the change in X, Phi,
% Psi moving from centerline out to the end.
